Introduction

- **Aim:** studying the interplay of fear-induced behaviour changes and imposed lockdown measures on pandemic severity
- **Model:** SEIHRD model
- **Lockdown:** modelled via imposed β reduction
- **Fear:** including both short and long term awareness, depending on the Deaths (D) compartment
- **Indicators:** position, height and number of the peaks, dynamics behaviour and cumulative deaths

Compartmental model

Differential equations:

$$\dot{s} = -\beta_{\text{eff}} i s$$

$$\dot{e} = \beta_{\text{eff}} i s - \mu e$$

$$\dot{i} = \mu e - \gamma i$$

$$\dot{r} = (1 - f_D) \gamma i + (1 - \nu) \gamma_H h$$

$$\dot{h} = f_D \gamma i - \gamma_H h$$

$$\dot{d} = \nu \gamma_H h$$

Parameters [1],[2],[3]:

R_0	3.49
μ	$1/2 \text{ d}^{-1}$
γ	$1/6 \text{ d}^{-1}$
f_D	0.08
γ_H	$1/10 \text{ d}^{-1}$
ν	0.47

Modelling fear

Fatality-induced behaviour changes are modelled via a reduction of the transmission rate β [2], both for the short and long term individual protective measures.

- the **short term** fear depends on the death rate $\delta = \dot{d}$:

$$\beta \rightarrow \frac{\beta}{1 + \left(\frac{\delta}{\delta_c}\right)^k},$$

the half-saturation constant δ_c regulates the death rate repercussion on behaviour and k regulates the sharpness of effect

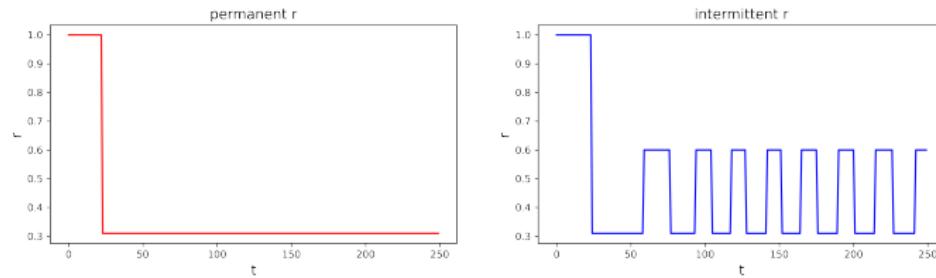

- the **long term** fear depends on the cumulative deaths d having D_c as half-saturation constant and the **cooperation** of both long and short terms reads:

$$\beta \rightarrow \frac{\beta}{1 + \left(\frac{\delta}{\delta_c}\right)^k + \left(\frac{d}{D_c}\right)^k}$$

Modelling lockdown

The lockdown effect is encoded in a multiplicative factor $r \leq 1$, which reduces the transmission rate $\beta \rightarrow r\beta$ [1]

The lockdown starts when a certain **threshold** in the hospitalized H/N it's reached:

Then, the **combined effect** of fear and lockdown, on the baseline transmission rate β , leads to an effective parameter β_{eff}

$$\beta_{\text{eff}} = \frac{r\beta}{1 + (\frac{\delta}{\delta_c})^k + (\frac{d}{D_c})^k}$$

Outline

- 1** Introduction
- 2** Model
- 3** Permanent lockdown - short term fear
- 4** Permanent lockdown - long term fear
- 5** Intermittent lockdown
- 6** Conclusion
- 7** Appendix

Permanent lockdown - short term fear

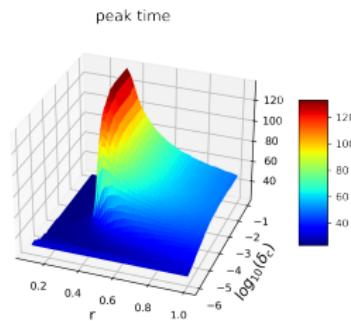

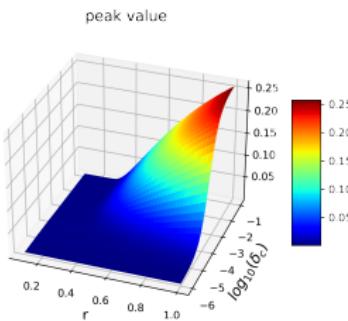

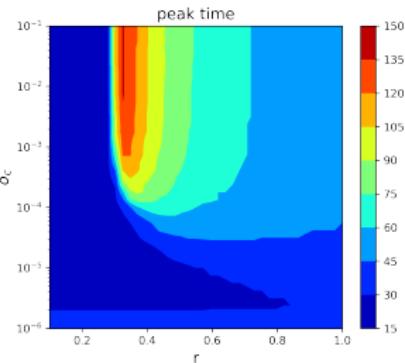

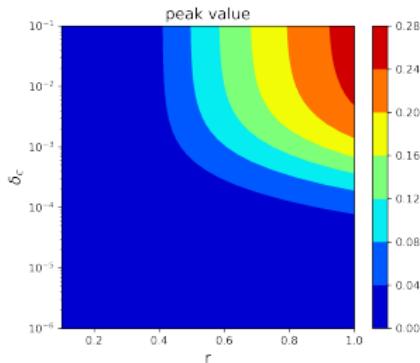

Model:

- permanent lockdown ($threshold = 10^{-4}$, $r_{perm} = 0.31$)
- short term awareness
- $k = 1$

$$\beta_{eff} = \frac{\beta r_{perm}}{1 + (\frac{\delta}{\delta_c})^k}$$

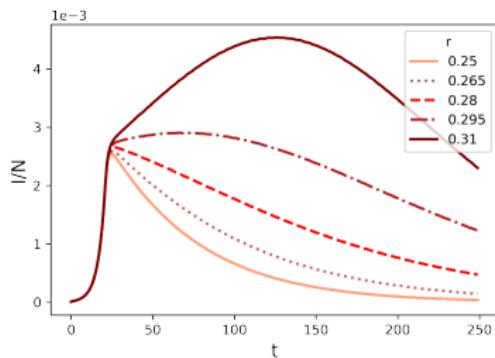

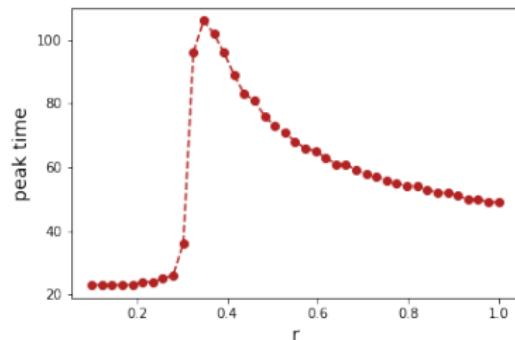

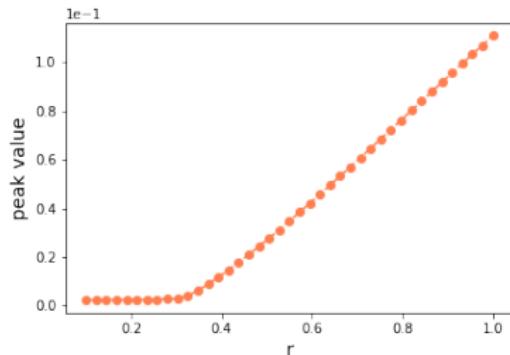

Permanent lockdown - short term fear

Parameters' space

Permanent lockdown - short term fear

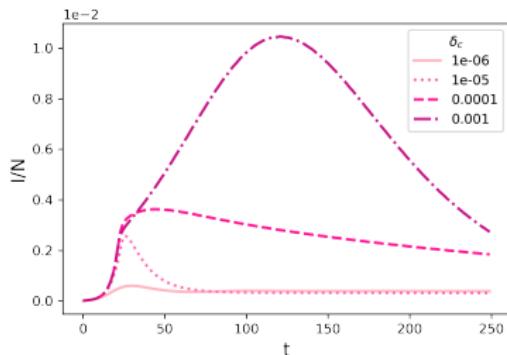

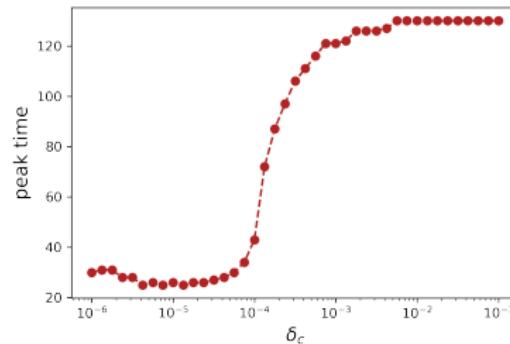

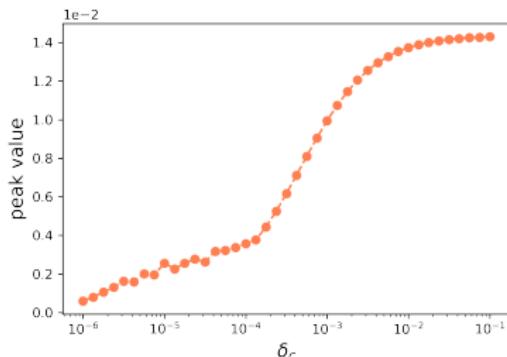

Peak value, peak time and incidence. Varying r , fixed $\delta_c = 0.01$

- existence of $r_c \sim 0.3$
- for $r < r_c$ early peak and epidemic extinction
- for $r > r_c$ late peak and higher incidence

Permanent lockdown - short term fear

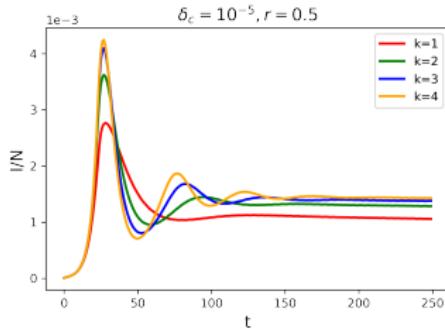

Peak value, peak time and incidence. Varying δ_c , fixed $r = 0.35$

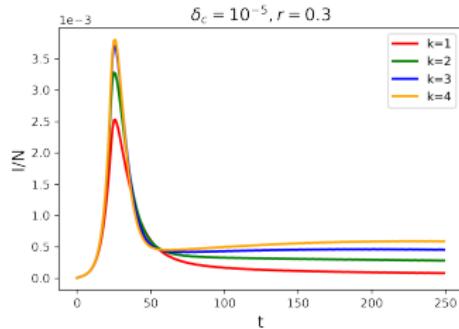

- distinct phases are not displayed
- increasing δ_c (low risk perception), higher incidence
- lower values of δ_c , exhibition of plateau

Permanent lockdown - short term fear

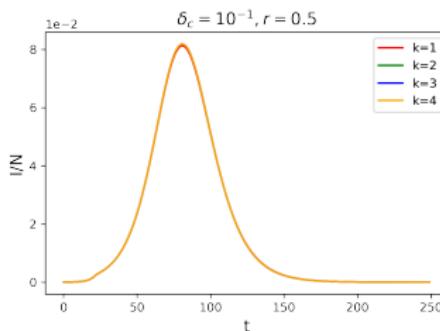

Incidence varying k

if δ_c is sufficiently high and $r > r_c$ oscillatory behavior appears

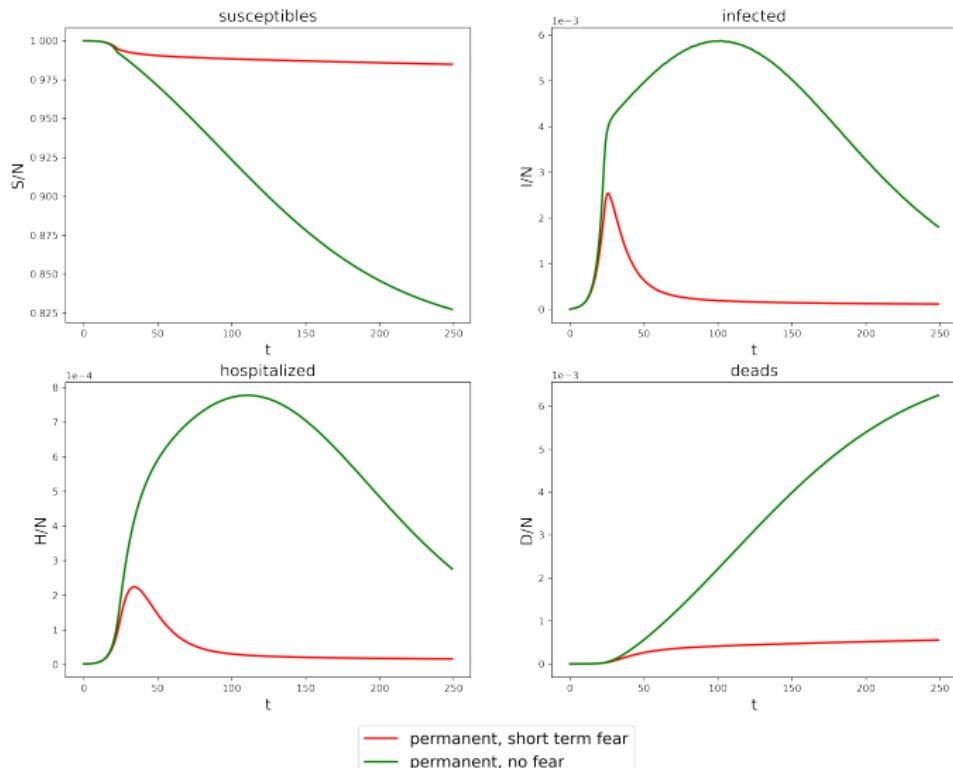

if δ_c is sufficiently high and $r \sim r_c$ the oscillations disappear, different k leads to different dynamics

k has not any influence for high value of δ_c (low fear)

Permanent lockdown - fear/no fear

$r=0.31$

Outline

- 1** Introduction
- 2** Model
- 3** Permanent lockdown - short term fear
- 4** Permanent lockdown - long term fear
- 5** Intermittent lockdown
- 6** Conclusion
- 7** Appendix

Permanent lockdown - long term fear

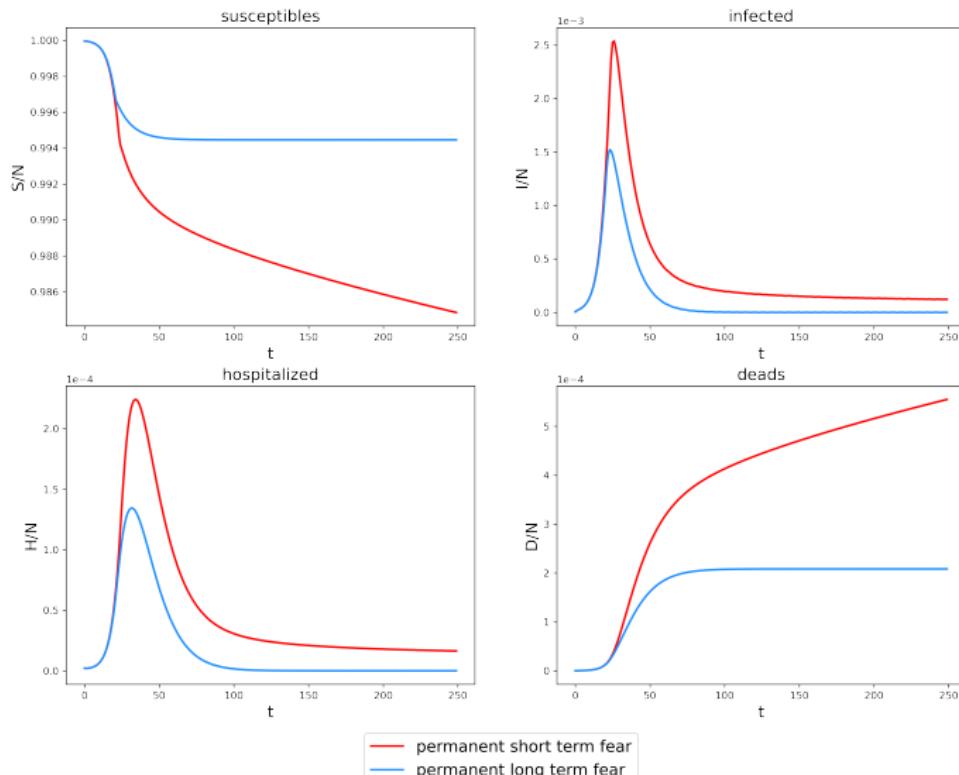

Model:

- permanent lockdown (*threshold* = 10^{-4})
- short-term awareness
- long-term awareness
- $k = 1$

$$\beta_{\text{eff}} = \frac{\beta r_{\text{perm}}}{1 + (\frac{\delta}{\delta_c})^k + (\frac{d}{D_c})^k}$$

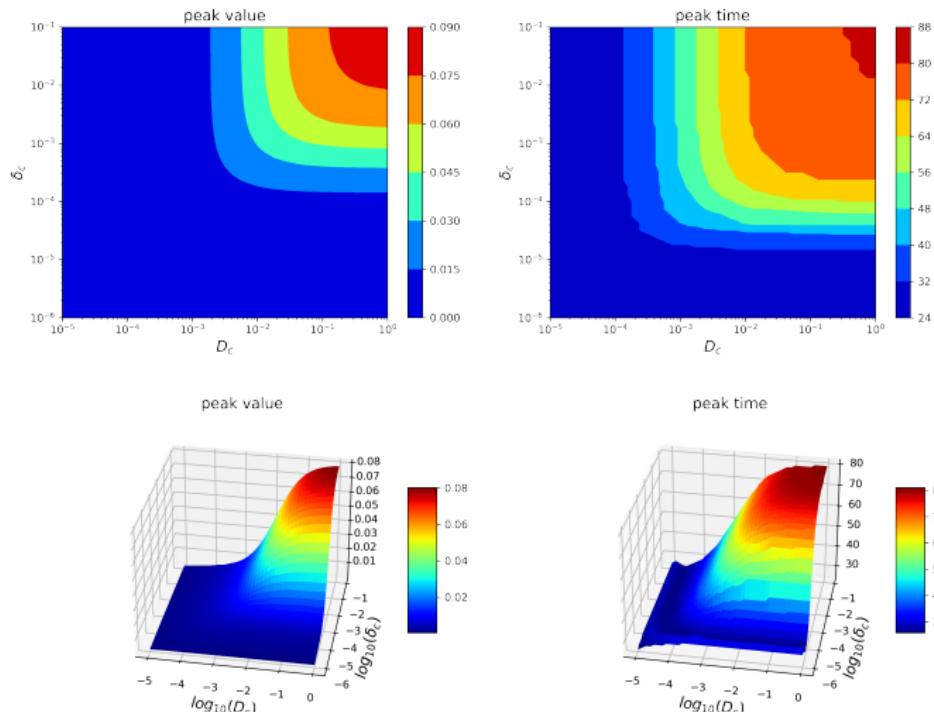

Permanent lockdown - long term fear

$r=0.31$

Permanent lockdown - long term fear

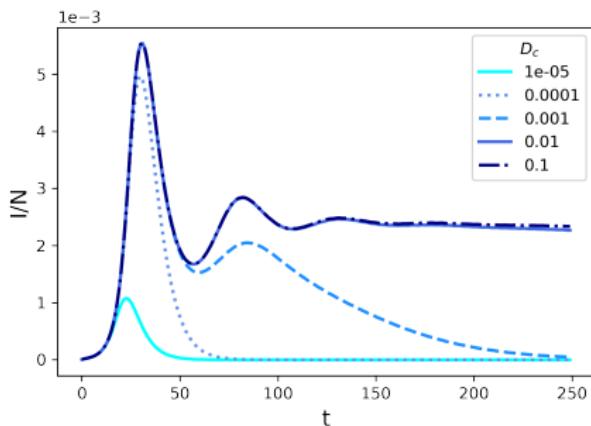

Parameters' space - $r = 0.5$

Permanent lockdown - long term fear

Incidence. Varying D_c , fixed $\delta_c = 10^{-5}$, $r = 0.5$

In high short-term-awareness situation, which is the effect of the long-term-awareness?

- high long term awareness (low D_c): low incidence with a peak at the beginning and then the epidemic gets extincted
- low long term awareness (high D_c): higher incidence, oscillatory dynamics after the peak and then it stabilizes in a plateau

- 2** Model
- 3** Permanent lockdown - short term fear
- 4** Permanent lockdown - long term fear
- 5** Intermittent lockdown
- 6** Conclusion
- 7** Appendix

Intermittent lockdown

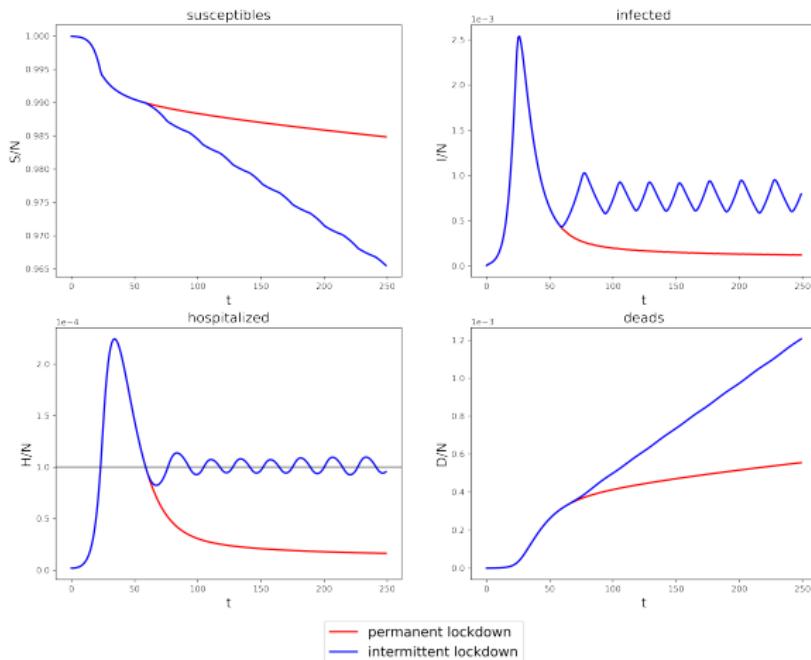

Model:

- intermittent lockdown ($threshold = 10^{-4}$, $r_{inter} = 0.31, 0.6$)
- short term awareness
- $k = 1$

$$\beta_{eff} = \frac{\beta r_{inter}}{1 + (\frac{\delta}{\delta_c})^k}$$

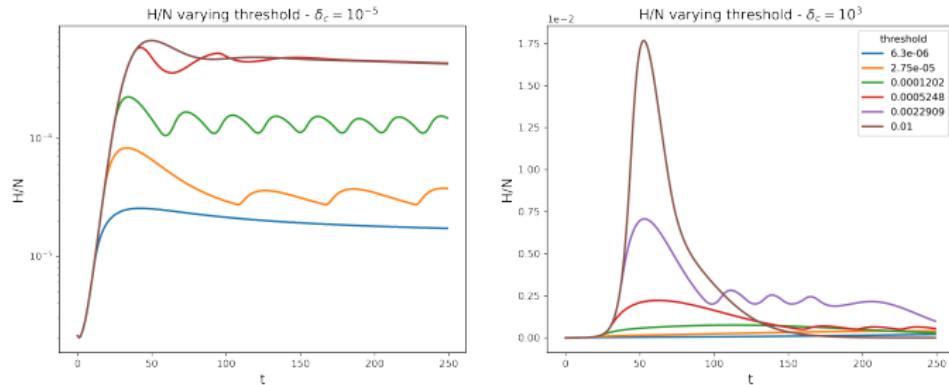

Intermittent lockdown

$r=0.31$

Intermittent lockdown

Hospitalized dynamics varying threshold

On the left, $\delta_c = 10^{-5} = \text{high risk perception}$:

- with intermediate thresholds, the dynamics oscillate around the threshold (due to intermittent lockdown)
- with thresholds $> 10^{-5}$, the threshold is never reached due to fear-induced behaviour changing

On the right, $\delta_c = 10^3 = \text{low risk perception}$: dynamics are no more limited by fear, thresholds are reached and lockdown effects are visible.

Conclusion

Studying the coordinated effect of lockdown restrictions and fear-driven behaviour is not an easy task, due to the interplay of several parameters, varying by several orders of magnitude.

- **Lockdown** measures are clearly impacting the stronger response in the pandemic containment, in particular if strict enough, to the point of making fear-induced behaviour changes inconsistent. Lighter restrictions allow fear-induced behaviour changes to rule the dynamics:
- **Short-term** attention, besides lowering the peak, give rise to plateaus in the incidence.
- **Long-term** attention can have a much stronger effect, to the point of leading to pandemic suppression.
- Clearly, a **permanent** lockdown, triggered when a certain hospitalized ratio is reached, allows to contain in a stricter way the epidemic spread. Anyway, it is not sustainable. Then, when imposing **intermittent** lockdown, an oscillatory behaviour around the threshold is obtained.

Thanks for the attention!
